Prenatal-onset GBS (POGBS) Sepsis is a Distinct Cause of Stillbirth and Perinatal Mortality

James A. McGregor, Marti Perhach
Group B Strept International

ABSTRACT

Background/Introduction
Intrauterine infection is increasingly recognized as a possibly preventable cause of stillbirth (SB). (McClure, Goldenberg, Semin Fetal Neonatal Med 2009, 14(4):182-9.)

Methods
Logic model analysis:
1) Conduct an expert systematic review and analysis of group B strep [GBS] disease knowledge in order to justify recognition of distinct Prenatal-onset GBS (POGBS) sepsis, distinct from Early onset-1 (EO) and Late-onset (LO) GBS infection
2) To correlate patient experiences, we conducted a quasi-experimental “internet commons” inquiry of parent contacts who had suffered GBS SB.
3) Computer-based national data bases were utilized to assess knowledge of GBS infectious disease.
4) An English language-seven-question patient survey was constructed, pretested, and disseminated to selected Group B Strept international contacts using the internet. No written consent was obtained.

Results
Much is known about GBS disease. Despite this knowledge, preventative regimes remain inconsistently applied, and in the best of circumstances are incompletely (85-90%) successful in reducing early onset GBS infection and do not address late onset or prenatal-onset GBS infections.

Conclusion
1) There is sufficient knowledge to support the CDC proposed (MMWR 2010, Volume 59/ RR-10) classification of prenatal-onset GBS POGBS sepsis as a distinct entity.
2) Our limited, uncontrolled investigation supports clinical notions that a) GBS loss or SB occurs in a bimodal gestational time distribution with the preponderance of cases occurring near term (POGBS); and b) that mothers do not reliably demonstrate fever or "febrile" findings of potentially lethal intrauterine infection. Other observations are precluded by the limited, uncontrolled nature of our retrospective, self-reported sample.

RESULTS
1) Prenatal-onset GBS intrauterine infection has been previously described (Katz, Tudela, Benirschke, others)
2) GBS is the commonest or among the commonest microorganisms isolated from normally "sterile" sites after passage through the vagina, between membranes, within placenta, cord blood, heart blood or spleen at autopsy.
3) GBS demonstrates pathophysiologic virulence capacities which can explain:
   a) Intrauterine infection with intact fetal membranes
   b) Invasive fetal infection
   c) Lethal factors (toxins, NETs, others) leading to placental or fetal death
   d) Multiple studies/analysis demonstrate feasibility and practicability of ACTIVE GBS VACCINATION

CONCLUSIONS
1) GBS, similar to other "perinatal pathogens," is an apparent cause of intrauterine infection (1° chorioamnionitis "CAM" or intraamniotic infection "IAI") can cause SB and very early PTB and possibly LM
2) Intrauterine infection or prenatal-onset GBS may explain GBS selective culture-based antibiotic chemoprophylaxis (IAP)
3) Recognition of PO-GBS-EOS can allow renewed experimentation in order to further reduce risks of GBS perinatal disease including rapid "Point of Care" microbial testing as well as adjuvant VACCINATION or other novel strategies

RECOMMENDATIONS
1) Reconvene well-funded national study group to explore novel strategies to further reduce risk of GBS neonatal disease burden
2) These strategies can be separate or in combination with culture-guided IAP:
   3) VACCINATION
   4) Microecologic
   5) Clinical Strategies - screen UTI/ASB
   6) Further refine microbials screening, i.e., early in pregnancy, UTI/ASB, and in labor or after ROM
   7) Improve operational procedures to enhance efficacy of IAP
